Usage of any items from the University of Cumbria’s institutional repository ‘Insight’ must conform to the following fair usage guidelines.

Any item and its associated metadata held in the University of Cumbria’s institutional repository Insight (unless stated otherwise on the metadata record) may be copied, displayed or performed, and stored in line with the JISC fair dealing guidelines (available here) for educational and not-for-profit activities provided that

• the authors, title and full bibliographic details of the item are cited clearly when any part of the work is referred to verbally or in the written form
  • a hyperlink/URL to the original Insight record of that item is included in any citations of the work
  • the content is not changed in any way
  • all files required for usage of the item are kept together with the main item file.

You may not

• sell any part of an item
• refer to any part of an item without citation
• amend any item or contextualise it in a way that will impugn the creator’s reputation
• remove or alter the copyright statement on an item.

The full policy can be found here. Alternatively contact the University of Cumbria Repository Editor by emailing insight@cumbria.ac.uk.
A rapidly ageing UK population and a corollary increase in the numbers of individuals suffering from dementia syndromes is causing a range of structural problems for healthcare services, and practice-oriented problems for frontline clinical staff[1]. A number of studies in the broader field of allied healthcare has recently emerged pertaining to the nuanced problems that will increasingly emerge as an output of working with patients with dementia, and the equally nuanced solutions that a practitioner might (or might not) find, especially around interpersonal communication[2-4]. Within this corpus, it is reported that junior practitioners of all orders are in a particular position of disadvantage[5,6], working with an ever-increasing number of patients with dementia, but without having yet accrued the levels of direct professional experience conventionally thought to be key to developing “expertise” in professional performance[7-9]. No research has to date, however, directly addressed this broad matter within the radiological professions.

Interpretative Phenomenological Analysis (IPA) was used to explore the everyday practical issues faced by junior medical imaging professionals (mean experience in clinical practice = 3.5 years) when handling patients with dementia. Employing a sample of N=6 such professionals, open-ended, semi-structured interviews were conducted (mean duration = 30 minutes). The questioning itself progressed from descriptive to analytical and evaluative. Data were analysed in line with the standard idiographic techniques of IPA[8]. Analysis revealed three superordinate themes, outlined below.

I. Confidence, experience and education

R1: “Dementia patients aren’t good at a lot of stuff...they get confused easily.”

R2: “...they’re just scared and confused.”

R4: “[I]f the department is mad busy...then I would [expect] a dementia patient to be problematic, and it’s going to take too much time.”

II. Practical and technological constraints on practice

R2: “[I]t’s definitely hard because...for instance...a chest x-ray should only take 3-5 minutes, but I’ve found [with a patient with dementia] it can take 20-30 minutes.”

R6: “[I]t is very fast paced...It puts a lot of pressure on the patient and the member of staff actually dealing with the patient...the major one that [affects] communication is the time.”

III. Complexities around carer input

R3: “[I brought them] into the room, asked them questions...so basically they can help communicate with the patient if the patient is more comfortable with them than us.”

R6: “You’re not guaranteed that the carer has a good relationship with that dementia patient, or can communicate with that dementia patient.”

Education for new professionals was seen as lacking in both quantity and context-relevance, with implications for professional confidence and legal ethical practice[9,10]. Carers/family were viewed as both a positive and negative force within an examination[4,11-13], and technological advances in radiography were taken to be clinically advantageous, but also sometimes actively detrimental to the effective interpersonal care of patients with dementia[6,14]. These issues may have import for the broader understanding of how a patient’s dementia can impact upon everyday practice for a new practitioner in range of fields, not least those naturally dissociated from dementia itself.
